

G8: Should prophylactic antibiotics be altered for patients who are carriers of methicillin-resistant *Staphylococcus aureus* (MRSA)?

Tianyi David Luo, Piret Mitt, Christopher E Pelt, Keita Morikane, Bingyun Li, Robert Molloy, Hitoshi Honda, Randi Silibovsky, Panayiotis Megaloikonmos, Amir Human Hoveidaei

Response/Recommendation:

Yes. Patients who are carriers of methicillin-resistant *Staphylococcus aureus* (MRSA) should receive an additional antibiotic with activity against MRSA in addition to cephalosporin.

Level of evidence: Limited

Delegate Vote:

Rationale:

Perioperative antibiotic prophylaxis is critical for reducing the risk of periprosthetic joint infections (PJI) and surgical site infections (SSI) in orthopaedic and spinal surgeries (1). Studies have explored the efficacy of combining vancomycin and cefazolin, particularly for preventing methicillin-resistant *Staphylococcus aureus* (MRSA) infections (2). While the addition of vancomycin to cefazolin was not superior to cefazolin and placebo in the prevention of surgical site infection in a population with low prevalence of MRSA colonization (3), the optimal antibiotic regimen that balances efficacy and potential adverse effects in MRSA carriers remains an active area of research.

This systematic review began with an initial screening of 482 article titles and abstracts from PubMed and Web of Science, resulting in 117 relevant studies. After full-text evaluation, 52 studies met the inclusion criteria, with 14 studies selected for data extraction and detailed analysis (4-17) (**Table 1**). There was no study that definitively assessed outcomes in confirmed MRSA carrier patients. Our meta-analysis found that cefazolin alone significantly reduces MRSA infections compared to non-cefazolin regimens ($P < 0.001$) (**Figure 1**). The combination of vancomycin and cefazolin provides superior protection, significantly lowering MRSA infection rates compared to cefazolin alone ($P = 0.002$) (**Figure 2**).

Three studies were not included in our meta-analysis:

1. **Takeuchi et al. (15):** Compared topical vancomycin versus ampicillin in patients undergoing thoracic and/or lumbar fusions. Infection with MRSA occurred in one patient (out of 114) in the ampicillin group, with no MRSA cases reported in the vancomycin group.
2. **Choi et al. (16):** Compared sulfamethoxazole/trimethoprim plus cefazolin or vancomycin (84 patients) versus cefazolin or vancomycin alone (511 patients) in spinal surgery. MRSA infection occurred in one patient in each group.
3. **Kanellakopoulou et al. (17):** Compared teicoplanin (278 patients) versus second-generation cephalosporins, β -lactam/ β -lactamase inhibitors, or ciprofloxacin (338 patients) in total hip/knee arthroplasty. MRSA infection was identified in one patient in the teicoplanin group and two in the comparison group (**Table 1**).

Conclusion:

The combination of vancomycin and cefazolin appears to offer superior protection against MRSA infections in orthopaedic and spinal surgeries compared to cefazolin alone. It is

worth noting that most included studies were retrospective cohort studies, and only a few randomized controlled trials were conducted. Moreover, since there are major variations in the patient population, interventions, types of orthopaedic procedures, and outcomes among included studies, it is hard to conclude that adding anti-MRSA agents or switching to anti-MRSA agents would be better than a traditional regimen of surgical antimicrobial prophylaxis (i.e., cefazolin) for MRSA carriers undergoing orthopaedic procedures. The potential risks of dual prophylaxis, such as increased antibiotic resistance and nephrotoxicity, must also be carefully considered. Given the absence of studies specifically addressing confirmed MRSA carriers, further high-quality research is essential to develop definitive guidelines for antibiotic prophylaxis in this patient population.
